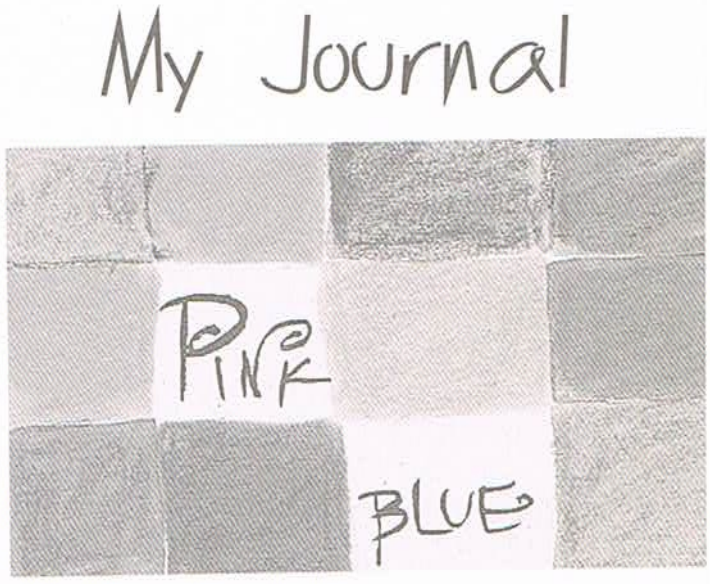
Programming Journal
1999 Yellow Patchwork

By Charlote Greenwood

Date written from 1999 to 2000



Property of:

Axel

@ - location URL for item
∴ appended after the Axel item.

_ - Variable

∴ example of variables.

- _dext (some variable)
- _dext@ localhost
- _dext@

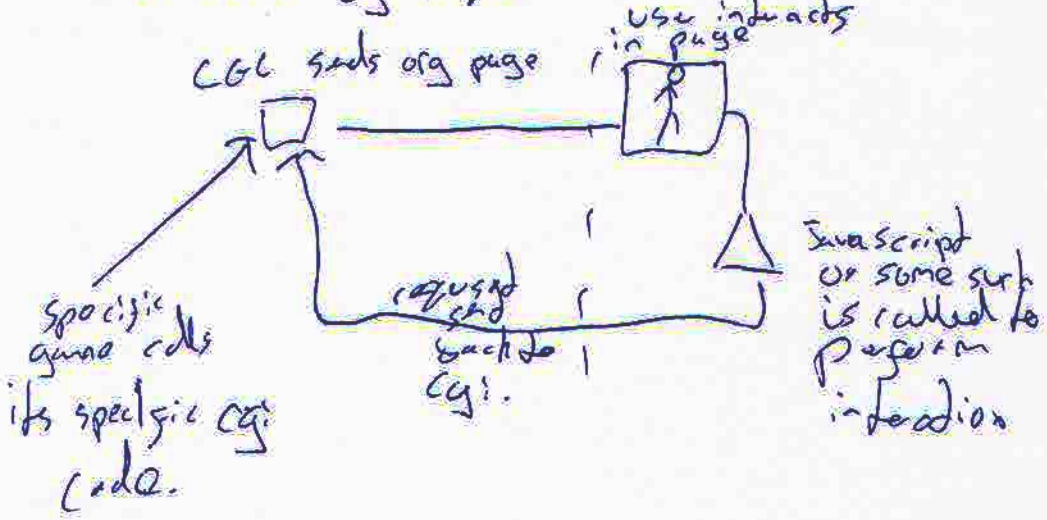
: axelprog1

remote servers use http to transfer the content of the variable from the base common path /axel-p therefore the path /axel-p must be avaible for http on the web domain. The colon command adds another path to this root. So :axelprog1 would be resaved to http:
axel-p/axelprog1/ and then the file 'dext' is brought back.

Note that web based variables are read only

2 word matches to produce a phrase.

For all games a cgi script will send the page to the user, where interaction will take place and then this will call up a new cgi request.



treenix datatypes

byte - 1 Byte
shord - 2 Bytes
int - 4 Bytes
dint - 8 Bytes
gint - 16 Bytes (?)

- char
- string

{ defined by location of user }

- single char is either 1 Byte or 2 Bytes.
- Character is from ASCII IBM(a) extended table, or UNICODE (a)

---

the above are all integers, floating points are use the a stadard integer head with the precision added afterward.

Floating point

m32int
m64int
m128int
m256int

float8
float16
float32

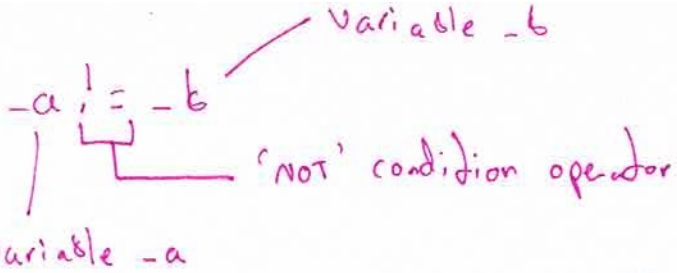
{2 Byte 1Byte} 0.0 → 65535.255

This would resolve do:
- as math would not be useable with 255 turning around.

0.0 → 65535.99

∴ Precision

1 Byte = 2 decimal places
2 Byte = 4 decimal places
4 Byte = 9 decimal places
8 Byte = 19 decimal places
& 16 Byte = 38 decimal places
& 32 Byte = 76
& 64 Byte = 152
& 128 Byte = 304
& 256 Byte = 608 decimal places



& the processing of the above statement calls the 'NOT' sub with the values of '-a' and '-b'. The sub compares these and the TRUE / FALSE value is placed in the current _condition system variable.

( ) brackets within a condition operate it's test operators.

@ a test sub is like any other runstat sub. It processes it's given information and then returns it's derived conditional true/false in the ouput structure.

Callers such as ~~Wend~~ while / If make use of the raw conditional data.

A single conditional sub processes any conditional argument, both simple and compound for and statement. The statement calls this major sub and then just checks the result.

10/100 MPS PCMCIA CARD

00 E0 98 71 49 27

I/O 300 H

INT 10 H

Treenie

'{' and '}' group statements that follow.

- a special sub is used to search for the closing '}' bracket.

'(' group computations.

'(' marks the start of a conditional if/while/etc... look for the '(' after them!?)

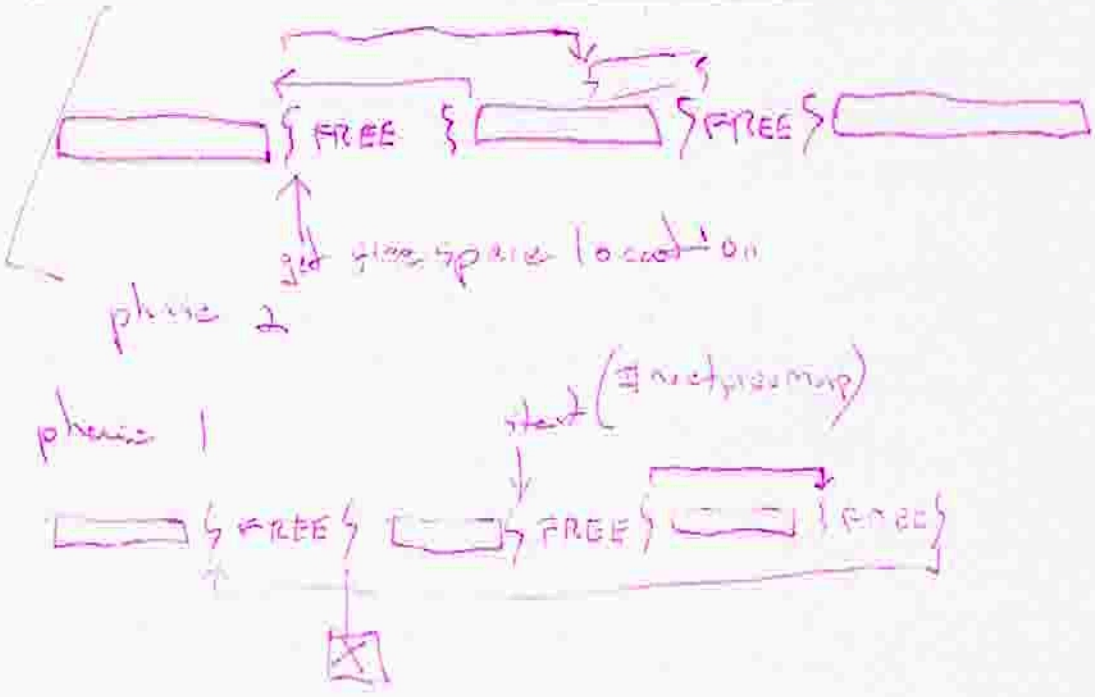
11/88 use the brackets to skip/return from a section.

(n ~ some statement condition) = returns true or false to the previous, so a group of conditions can be tested and resolved to one value.

Variables

all variables must have an allocation within the [UV] name store.

allocation 2 - can not be stored.
allocation 3. system argument / temporary store that is erased/freed at the end of processing of the line.



Beyond! Teenie 32 Bit Numerics

* Those are integers that can be signed or unsigned.

64 Bit - (long) dint
128 Bit - mega
256 Bit - giga
512 Bit - tera
1024 Bit - ultra

None of these are handled by the system's built in math functions. They do assume a 32 bit integer math processing capability is present however.

These large values must have the following functions:

- additions
- subtractions
- multiply
- division

} — these are then called by higher functions.

- print these values to a string

→ count (B) 2 spaces from right
+ count (A) 2 spaces from right
= 4 padded zeros.

[2×2] = 4
+ padding
∴ 40000

Each column is its own ushort store.

∴ 4 would be stored in ushort [4] (padding - 1)

at the end of the multiply run.
each ushort is run through right to left. The <10 digit is taken and the MSD is passed (added to) the next ushort. What's left at the end is put into the string.

string8 - Romanized text

string16 - Unicode

condition testing is a built in process that returns a true/false value when using the test operators.

for

condition

while ( ) {

execution is branched here

Do statements in brackets while condition is true

(3) - this final bracket should be indeed at start to save un needed processing.

{ Bracket is linked to the connected statement

The presence of a bracket '{' causes the appropiate tokens to be stored and the runstat will branch after testing the condition is true and execute the statements until another '}' is come accross.
